We describe a cognitive disability that occurred over a ten-month period in a child with a progressive brain disorder. The disability progressed from a deficit in understanding language in the first five months to loss of all language and memory function. Although the child was always aware of language and information processing ability, he was unable to communicate. Between five and ten months after illness onset he began to develop a specific repertoire of concrete and abstract words, which allowed him to communicate when his mother or other carers spent long periods of time with him. However, he was also able to use this 'language' to express distress when difficulties with daily living, for example, arising from social interactions became too intense. Because he had always been a bright child, his parents questioned whether their son was intellectually handicapped. In contrast, a comparison group of normal children, who had similar levels of education, did not develop language using a concrete conceptual level. The families of the handicapped children had more frequent disagreements with their children and there were more physical fights than in a group of normal children. In the discussions about possible cognitive
